

Additional Techniques

1. Angular services and DI
2. Calling REST services

Demo app: `AngularDev/Demos/06-AdditionalTechniques/DemoApp`

To install: `npm install`

To run: `ng serve`

Section 1: Angular Services and DI

- Overview
- Dependency injection
- Services and DI example
- Generating a service
- Implementing the service
- Injecting the service
- Singleton service instance

Overview

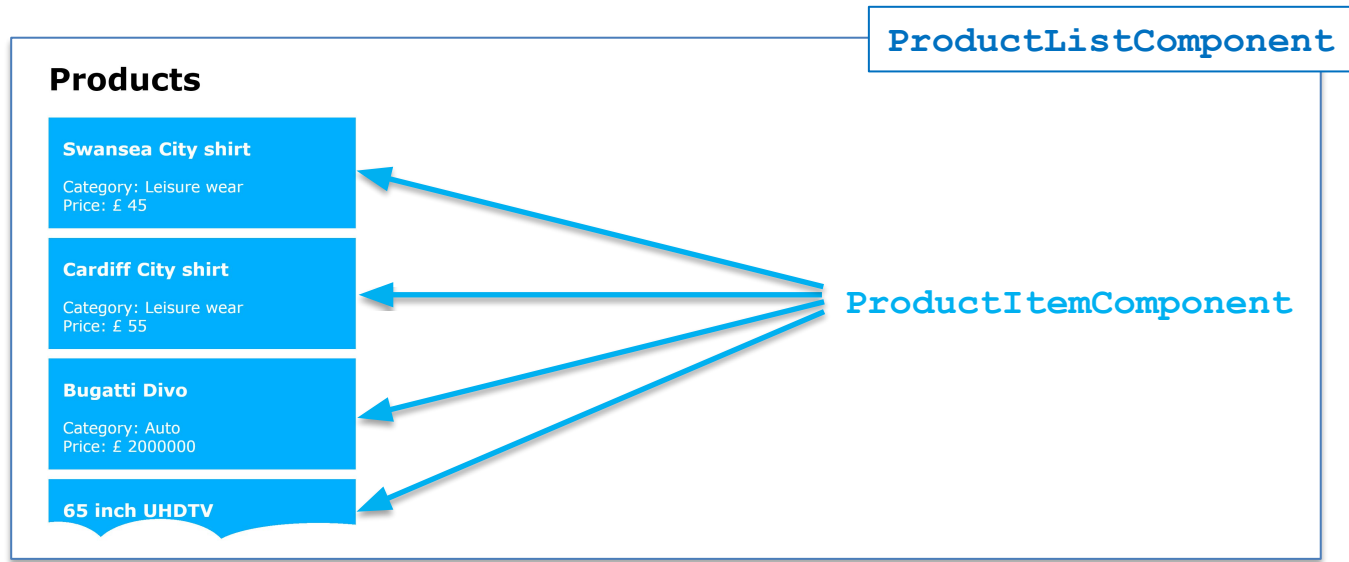

- Don't put this kind of code in your components:
 - Calling REST services
 - Interacting with Web Sockets
 - Accessing state in local storage
 - Etc.
- Instead:
 - Put this functionality in reusable *service classes*
 - Inject services into components, as needed

Dependency Injection

- Angular supports constructor dependency injection
 - In your component constructor, define the services you want to be injected as parameters
 - Angular will inject suitable objects
- How does dependency injection work in Angular?
 - By default, the root module *provides* (creates) services
 - Angular injects services into component constructors

Services and DI Example

- Let's see an example of services and DI
 - In the demo app, click the **Services and DI** link

Generating a Service

- We've put the responsibility for "getting products" into the `ProductService` class
- We used Angular CLI to generate the `ProductService` class as follows:

```
ng g service product
```

```
CREATE src/app/product.service.spec.ts (362 bytes)  
CREATE src/app/product.service.ts (136 bytes)
```

Implementing the Service

- Here's our implementation of ProductService
 - Note the `providedIn` property in `@Injectable()`
 - Specifies the service will be provided by 'root', i.e. the root module in the application

```
import { Injectable } from '@angular/core';  
import { Product } from '../product'
```

```
@Injectable({  
  providedIn: 'root'  
})
```

```
export class ProductService {  
  getProducts(): Array<Product> {  
    var products: Array<Product> = [...];  
    return products;  
  }  
}
```

`product.service.ts`

Injecting the Service

- You can inject service(s) into a component constructor as follows:

```
import { ProductService } from '../product.service'
...

@Component(...)
export class ProductListComponent {

  products: Array<Product>;

  constructor(productService: ProductService) {
    this.products = productService.getProducts();
  }
}
```

product-list.component.ts

Singleton Service Instances

- Recall the service class is decorated as follows:

```
@Injectable({  
  providedIn: 'root'  
})  
export class ProductService {...}
```

- This means the service object is *provided* (created) by the root module
 - The service object is created as a singleton
 - The same instance will be injected into all components
 - Singleton is common for "infrastructure" services

Section 2: Calling REST Services

- Overview
- REST service example
- Pinging the REST service
- Example Angular REST client
- Adding support for REST clients
- Calling a REST service
- Consuming the REST result
- Displaying the REST result

Overview

- REST services are resource-centric services
 - Endpoints (URLs) represent resources
 - Endpoints are accessible via standard HTTP(S)
 - Endpoints can be represented in a variety of formats, e.g. JSON, XML, plain text, etc.
- Rest services play a vital role in Angular applications
 - SPAs invoke REST services to get/update state
 - Use JSON data (or maybe XML)

REST Service Example

- We've implemented a simple REST service
 - Returns product data
- The REST service is a Node.js app, run as follows:
 - Open a Command Prompt window in the `Server` folder
 - Run the following commands:

```
npm install
```

```
npm start
```

Pinging the REST Service

- To ping the REST service, open a browser window and enter the following URL:
 - <http://localhost:8080/api/products>

A screenshot of a web browser window. The address bar shows 'localhost:8080/api/products'. The page content displays a JSON array of product objects. The browser interface includes a tab, back/forward buttons, a refresh button, and search, star, and menu icons.

```
[{"id":0,"description":"Swansea City shirt","category":"Leisure wear","price":45}, {"id":1,"description":"Cardiff City shirt","category":"Leisure wear","price":5}, {"id":2,"description":"Bugatti Chiron","category":"Auto","price":2000000}, {"id":3,"description":"65 inch UHDTV","category":"TV/Audio","price":1800}, {"id":4,"description":"Carving skis","category":"Sports equipment","price":350}, {"id":5,"description":"Ski boots","category":"Sports equipment","price":150}]
```

Example Angular REST Client

- Let's see an example of an Angular REST client
 - In the demo app, click the **Angular REST client** link

Products (technique 1)	Products (technique 2)
Swansea City shirt Category: Leisure wear Price: £ 45	Swansea City shirt Category: Leisure wear Price: £ 45
Cardiff City shirt Category: Leisure wear Price: £ 5	Cardiff City shirt Category: Leisure wear Price: £ 5
Bugatti Chiron Category: Auto Price: £ 2000000	Bugatti Chiron Category: Auto Price: £ 2000000
65 inch UHD TV Category: TV/Audio Price: £ 1800	65 inch UHD TV Category: TV/Audio Price: £ 1800
Carving skis Category: Sports equipment Price: £ 350	Carving skis Category: Sports equipment Price: £ 350
Ski boots Category: Sports equipment Price: £ 150	Ski boots Category: Sports equipment Price: £ 150

Adding Support for REST Clients

- If you want your Angular app to call a REST service, your module must import `HttpClientModule`

```
import { HttpClientModule } from '@angular/common/http';  
...  
  
@NgModule({  
  declarations: [...],  
  imports: [HttpClientModule, BrowserModule, AppRoutingModule],  
  providers: [],  
  bootstrap: [AppComponent]  
})  
export class AppModule { }
```

`app.module.ts`

Calling a REST Service (1 of 2)

- To call a REST service from Angular:
 - Inject the standard `HttpClient` service
 - Call `get()`, `put()`, `post()`, `delete()`
- For full details, see:
 - <https://angular.io/api/common/http/HttpClient>

Calling a REST Service (2 of 2)

- We've defined an Angular service class to encapsulate calls to the "get products" REST endpoint
 - The call is asynchronous, returns an `Observable<T>`

```
import { HttpClient } from '@angular/common/http';
import { Observable } from 'rxjs';
...
@Injectable({providedIn: 'root'})
export class ProductViaRestService {

  private baseUrl = 'http://localhost:8080/api/products';

  constructor(private http: HttpClient) {}

  getProducts(): Observable<Array<Product>> {
    return this.http.get(this.baseUrl) as Observable<Array<Product>>;
  }
}
```

product-via-rest.service.ts

Consuming the REST Result

- We consume the `Observable<T>` in 2 ways...

```
@Component(...)
export class ProductListViaRestComponent implements OnInit {

    productsTechnique1!: Observable<Array<Product>>;
    productsTechnique2!: Array<Product>;

    constructor(private productViaRestService: ProductViaRestService) {}

    ngOnInit(): void {
        this.productsTechnique1 = this.productViaRestService.getProducts();

        this.productViaRestService.getProducts().subscribe({
            next: (data:any) => this.productsTechnique2 = data,
            error: (_,any) => console.log("Error")
        });
    }
}
```

product-list-via-rest.component.ts

Displaying the REST Result

- We display the REST result in 2 ways...

```
<div>
  <div class="halfColumn">
    <h1>Products (technique 1)</h1>
    <div *ngFor="let p of productsTechnique1 | async">
      <app-product-item [product]="p"></app-product-item>
    </div>
  </div>

  <div class="halfColumn">
    <h1>Products (technique 2)</h1>
    <div *ngFor="let p of productsTechnique2">
      <app-product-item [product]="p"></app-product-item>
    </div>
  </div>
</div>
```
